STOREFRONT UX AUDIT · FULL JOURNEY

Hayaan Market

A mobile-first walkthrough of the complete shopping journey — discovery, search, product pages, cart, checkout and post-purchase — benchmarked against leading global marketplaces, with ten prioritized findings, severity and effort ratings, and concrete fixes.

Prepared by Super Z (Z.ai)

1. Executive Summary

This audit reviews the complete shopping experience of **hayaan.co** - the Hayaan Market storefront - from first landing to post-purchase. It combines a live, device-level walkthrough (mobile 390×844 as the primary device, desktop 1440×900 as a secondary pass) with a line-by-line review of the storefront codebase, so that every finding separates *what is missing* from *what exists but underperforms*. The experience is benchmarked against patterns shoppers already know from leading global marketplaces such as Amazon and Jumia.

The overall picture is strong for a store at this stage: the fundamentals are genuinely well built. Product discovery through search was just upgraded with a live suggestions panel; product pages expose quantity, stock, per-district delivery fees and a verified-purchase review system; checkout hands off to Sifalo Pay with sensible server-side verification; and the site ships full Somali translations alongside English. The gaps that remain are concentrated where revenue leaks: the moments around the cart, the checkout walls, and the promises the site makes that it does not yet keep (order tracking, confirmation email, policy pages).

10	5	2
findings across the full journey	rated Critical or High	quick wins selected for same-day fix

The single most consequential finding is **F1: there is no guest cart and no guest checkout**. A first-time visitor must create an account before they can even add a product to the cart, which checkout research (Baymard Institute) consistently identifies as one of the largest preventable causes of cart abandonment. The two findings with the best impact-to-effort ratio - related products on the product page and a sticky add-to-cart bar on mobile - were selected for immediate implementation as quick wins.

2. Method and Scope

Live walkthrough. The production site was driven with a scripted, real-input browser session (clicks and keystrokes through the actual input pipeline, not synthetic events) at phone size first: home, search with live suggestions, search results, category page, product detail, cart drawer and footer. A desktop pass re-checked the product page layout. Every stop was screenshotted; the key captures appear in Appendix A. The walkthrough was repeated against the live domain, so all observations reflect what real shoppers in Somalia see today.

Code review. The storefront source (Next.js 16 app, components, hooks and server libraries) was inventoried feature by feature - catalog, cart, checkout, payments, accounts, reviews, wishlist, i18n,

feedback states and mobile patterns - to distinguish true absences from features that exist but are reached differently than a marketplace-standard shopper expects. Deliberate business decisions found in the code (fixed USD pricing with no VAT, district-based delivery fees, Sifalo Pay as the single payment path, removal of the free-shipping threshold) are treated as design intent, not defects.

Scope. Full journey: home and discovery, search, category browsing, product detail, cart, checkout, payment, orders and post-purchase, plus trust and support surfaces (footer, FAQ, WhatsApp). Out of scope: backend operations, the admin panel, marketing surfaces (/deals, /quote, /investors) beyond their UX touchpoints, and price/merchandising strategy.

3. What Is Working Well

Before listing gaps, it is worth being precise about what already meets or exceeds the marketplace standard, because these strengths should be preserved while the fixes land:

- **Search with live suggestions.** Typing in the header search opens an in-viewport panel with ranked matches, prices and a truthful result count, on both desktop and mobile (shipped as the previous task). Suggestions share the exact haystack of the grid filter, so the count never contradicts the grid.
- **Honest, verified social proof.** The review system supports reading and writing, star distribution, editing your own review, and a Verified-purchase badge computed server-side from paid orders - a trust mechanic many larger stores fake.
- **Delivery cost transparency.** The product page previews the exact delivery fee per Mogadishu district (20 districts priced) before checkout, using the same table the checkout charges - no bill shock.
- **Server-side cart and order integrity.** Carts live in the database per account, orders are created before payment hand-off, and the Sifalo return page re-verifies payment status server-side with categorized error recovery.
- **Full bilingual experience.** Roughly 550 UI strings are mirrored in Somali, rendered server-side from a language cookie, with localized API errors - rare depth for a store at this stage.
- **Mobile-latency engineering.** Prerendering, back/forward-cache compatibility, scroll restoration, an SSR catalog slice and skeleton loaders give the storefront a fast feel on cheap Android phones.
- **Feedback states everywhere.** Toasts, skeletons, empty states with recovery actions, and localized error copy are consistently implemented across grid, cart, orders and wishlist.

The consequence for prioritization: none of the findings below require re-architecting. They attach cleanly to an already solid base.

4. Priority Matrix

Findings are ordered by expected impact on conversion and retention, weighted by implementation effort (S = half a day or less, M = one to three days, L = multi-week or architectural). Severity reflects risk to revenue and trust, not code quality.

#	Finding	Journey stage	Severity	Effort
F1	No guest cart or guest checkout - account required before add-to-cart	Cart / Checkout	**Critical**	L
F2	No order tracking timeline - status badges only	Post-purchase	**High**	M
F3	No confirmation email or SMS to the customer	Post-purchase	**High**	M
F4	Dead footer links; no privacy, terms or help pages	Trust	**High**	S
F5	No related products or cross-sell on the product page	Product page	**High**	S-M
F6	No sticky add-to-cart bar on mobile product pages	Product page	**Medium-High**	S
F10	No password reset or account recovery	Account	**Medium-High**	M
F7	Hero pushes the catalog about 1.3 viewports down on mobile	Discovery	**Medium**	S-M
F8	No advanced filters or pagination for a growing catalog	Discovery	**Medium**	M
F9	Product gallery lacks zoom, lightbox and swipe	Product page	Low-Medium	S-M

Table 1. Findings ordered by priority. Severity: risk to revenue and trust. Effort: S half-day, M 1-3 days, L multi-week.

5. Findings

Each finding follows the same structure: what the live walkthrough or the code shows, why it matters commercially, the marketplace pattern it benchmarked against, and a concrete, scoped recommendation. Severity colors match Table 1.

F1 No guest cart or guest checkout

Severity: Critical · **Effort:** L · **Journey stage:** Cart / Checkout

What we saw. The cart is server-side and keyed to a signed-in account: tapping the quick-add button as a guest opens the sign-in modal instead of adding the item, and the cart API returns 401 for guests. Checkout then hard-gates again with a sign-in wall. A shopper who only wants to buy one phone case must create an account - email or Google - before the funnel even starts.

Why it matters. Forced account creation is one of the most reliably measured conversion killers in e-commerce. Baymard Institute's multi-year checkout research consistently attributes roughly one in five cart abandonments to sites requiring account creation. For a new store competing for first-time trust, the tax lands on exactly the visitors with the least loyalty.

Benchmark. Amazon, Jumia and AliExpress all allow adding to cart and starting checkout without an account; registration is offered after the order or alongside it as an optional step.

Recommendation. Introduce a guest cart (a cookie-keyed guest session row server-side, or a localStorage cart merged at sign-in) and a guest checkout path that captures phone number and address, then optionally creates the account on the confirmation screen. Keep the account requirement for wishlist, reviews and order history, where it genuinely serves the shopper.

F2 No order tracking timeline

Severity: High · **Effort:** M · **Journey stage:** Post-purchase

What we saw. The hero promises Track every order, but the orders view is a list of cards with status badges (pending, paid, shipped, delivered) and a live re-check of Sifalo payment status. There is no tracking page, no timeline, no tracking number or courier field, and no per-order detail view.

Why it matters. Post-purchase anxiety is highest exactly after payment - the moment a marketplace-standard shopper looks for a Where is my order answer. Supporting that WhatsApp volume manually costs more than exposing status in-product, and a kept promise here compounds trust for repeat purchases.

Benchmark. Amazon and Jumia expose a step timeline (ordered, packed, out for delivery, delivered) per order, with estimated dates and, where available, courier tracking numbers.

Recommendation. Ship a pragmatic version first: an order detail view with a four-step timeline driven by the existing status field and last-updated timestamps, reachable from the orders list and from the payment success screen. Add courier and tracking-number fields to the admin fulfillment flow so the timeline can display them when the owner has them.

F3 No confirmation email or SMS to the customer

Severity: High · **Effort:** M · **Journey stage:** Post-purchase

What we saw. The payment success screen tells the shopper a confirmation email is on its way, but no transactional email is sent anywhere in the codebase - the only email infrastructure is owner-facing lead notifications via Resend. The shopper's only receipt is the success screen and the orders list.

Why it matters. A promised email that never arrives is worse than no promise: it erodes trust at the exact moment the store should be reinforcing it, and it leaves the shopper with no durable record of the order reference or totals outside the site session.

Benchmark. Every major marketplace sends an order confirmation within seconds of payment, restating items, totals, delivery expectation and support contact.

Recommendation. Send the confirmation email from the payment-verified server hook (Resend is already integrated) with order reference, items, totals, delivery district and fee, and a deep link to the order. A short SMS variant for Mogadishu shoppers is a strong second step given phone-first behavior; either closes the promise gap.

F4 Dead footer links; no policy pages

Severity: High · **Effort:** S · **Journey stage:** Trust

What we saw. In the footer, Help center, Shipping info and Track your order render as non-clickable text, as do Privacy, Terms and Cookies; the social icons point at #. The live footer link inventory is: shop, blog, quotes, deal alerts, investors and a mailto address - everything a shopper would read before trusting a new store with money is dead text.

Why it matters. Policy pages are among the most-read pages for first-time buyers deciding whether a store is legitimate - and they are required groundwork for payments and any future advertising or app-store submission. Dead links actively signal the opposite of the trust the copy claims.

Benchmark. Amazon and Jumia anchor their footers with shipping, returns, privacy and terms pages; every footer link resolves.

Recommendation. Either ship four short pages (Privacy, Terms, Shipping and delivery, Returns) or rewire the labels to the existing FAQ answers, which already cover delivery costs, payment and contact - then make every footer item a real link. This is the cheapest trust win on the list.

F5 No related products or cross-sell on the product page

Severity: High · **Effort:** S-M · **Journey stage:** Product page

What we saw. The product page ends at the reviews section. There is no related products, no customers also viewed, no complementary items - a shopper interested in a Galaxy A18 gets no prompting toward a case, charger or alternative phone, and a dead-ended shopper leaves to search elsewhere.

Why it matters. Cross-sell rails are among the highest-leverage surfaces in retail UX; widely cited estimates attribute roughly a third of Amazon's revenue to its recommendation engine. For Hayaan, the same-catalog rail raises items per order and pages per session with zero new inventory.

Benchmark. Amazon (Frequently bought together, Customers also viewed) and Jumia (You may also like) both treat related products as a mandatory PDP section.

Recommendation. A You may also like rail of four to six same-category products (excluding the current one), computed from the already-loaded catalog the same way the search suggestions are - zero new network calls. **This finding was selected as a same-day quick win.**

F6 No sticky add-to-cart on mobile product pages

Severity: Medium-High · **Effort:** S · **Journey stage:** Product page

What we saw. On a phone, the add-to-cart and buy-now buttons sit in the buy box near the top of the product page. Rich descriptions (the Galaxy A18 page runs several screens of specifications, delivery details, FAQ and reviews) push the user far past the buttons; there is no sticky bar to recover the action, so an interested reader must scroll back up to buy.

Why it matters. The longer a shopper stays engaged on a product page, the further the buy action travels out of reach. Marketplaces solve this with a compact sticky bar that appears once the buy box scrolls away - it keeps price, name and Add to cart one thumb-tap away at all times.

Benchmark. Amazon and Jumia both pin a compact buy bar (image, price, add-to-cart) to the viewport bottom on mobile product pages.

Recommendation. A mobile-only sticky bar that slides in after the buy box leaves the viewport: thumbnail, name, price and an Add to cart button reusing the existing cart action and toast feedback. **This finding was selected as a same-day quick win.**

F10 No password reset or account recovery

Severity: Medium-High · **Effort:** M · **Journey stage:** Account

What we saw. The auth modal offers email-and-password sign-in and Google OAuth, but there is no forgot-password flow, no email verification round-trip, and no way to recover an email-password account whose password is forgotten. The only escape for a locked-out shopper is to remember the password or

have previously used Google sign-in.

Why it matters. Every locked-out shopper with an order in flight becomes a support conversation or an abandoned order. As the customer base grows, password reset stops being an edge case and becomes a weekly occurrence.

Benchmark. Amazon and Jumia both recover accounts through a one-tap email or phone OTP flow; email-password commerce without recovery is effectively unheard of.

Recommendation. Wire Supabase's built-in password-reset email into the auth modal (send magic link, land on a set-new-password view) and add the forgot link next to the password field. Email verification for new accounts can follow in the same work.

F7 Hero pushes the catalog about 1.3 viewports down on mobile

Severity: Medium · **Effort:** S-M · **Journey stage:** Discovery

What we saw. On a 390×844 phone, the mobile hero - badge, two-line headline, paragraph, two calls to action, three reassurance rows and an image collage - fills roughly one and a third viewports before the category pills and first product cards appear. Search now answers instantly in-viewport (previous task), but a shopper who browses instead of searching scrolls past marketing on every returning visit.

Why it matters. Marketplace-standard mobile homes lead with a search bar and category or product content within the first screen; brand storytelling earns a smaller share of the viewport. First impressions still matter - the hero is well made - but it should not tax every browse session.

Benchmark. Jumia's mobile home shows search, category tiles and deals within the first screen; Amazon leads with a compact header and product rails.

Recommendation. On mobile only, compress the hero: shorten the headline block, move the collage below the category pills, or render a compact hero variant with the pill row visible above the fold. Desktop can keep the current composition.

F8 No advanced filters or pagination for a growing catalog

Severity: Medium · **Effort:** M · **Journey stage:** Discovery

What we saw. The grid offers category pills and a sort select (featured, price, rating) but no price-range, brand, rating or availability filters, and no pagination or infinite scroll - the whole filtered catalog (up to 500 items; the phones category alone renders 65 cards, 82 results match a phone search) renders at once.

Why it matters. At the current catalog size this mostly costs scroll depth, but every added product makes both the DOM and the decision process heavier. Shoppers arriving from search engines expect to narrow by price first, and page-weight grows linearly with the catalog.

Benchmark. Amazon and Jumia expose price bands, brand and rating filters with applied-filter chips, and paginate or lazy-load result lists.

Recommendation. In order: a price-range filter (client-side first, server-side when the catalog grows), an in-stock toggle, then brand facets once a category exceeds about fifty items. Introduce paged rendering (for example twenty-four cards with a Load more control) behind the same filter state.

F9 Product gallery lacks zoom, lightbox and swipe

Severity: Low-Medium · **Effort:** S-M · **Journey stage:** Product page

What we saw. The gallery shows a main image with a thumbnail strip; on mobile the main image is fixed-size with no pinch zoom, no fullscreen lightbox and no swipe between images. Product photography is the closest a shopper gets to handling the goods - for electronics, reading the serial region, ports and accessories in the photo is part of the decision.

Why it matters. Marketplaces treat image inspection as a solved expectation; its absence reads as a constraint of a smaller store and increases hesitation on higher-ticket items like phones.

Benchmark. Amazon and Jumia both offer fullscreen galleries with swipe and zoom as the default touch interaction.

Recommendation. A touch lightbox (open on main-image tap, swipe between images, double-tap or pinch to zoom) over the existing image list; keep the thumbnail strip for desktop. Low risk, purely client-side, and immediately felt on every product page.

6. Delivery Roadmap

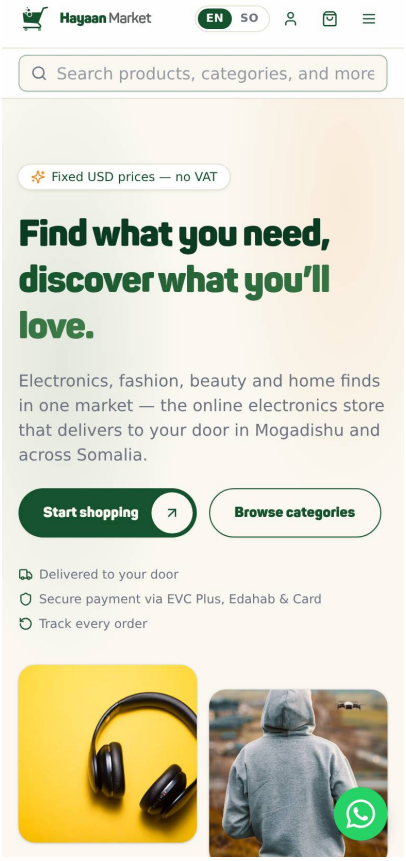

Sequenced by dependency and payoff. The quick wins are already in motion; the structural items are independent and can follow in any order the owner prefers.

Wave	Items	Outcome
Now (this week)	F5 related-products rail; F6 mobile sticky add-to-cart (shipped as same-day quick wins); F4 policy and help pages rewired	Higher items per order; buy action always reachable; footer trust restored
Next (2-4 weeks)	F3 confirmation email on payment verify; F2 order timeline view; F10 password reset	Post-purchase promise kept; support load down; no more lock-outs
Later (1-2 months)	F1 guest cart and guest checkout; F7 compact mobile hero; F8 price filter and load-more; F9 gallery lightbox	Friction-free first purchase; browse-first discovery scales with the catalog

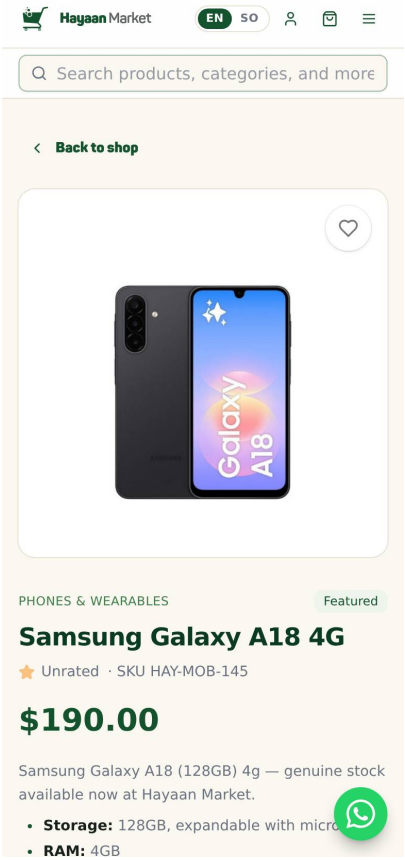

Table 2. Suggested sequencing. F1 is the largest build and benefits from a design pass on guest identity before implementation.

7. Appendix A: Evidence Screenshots

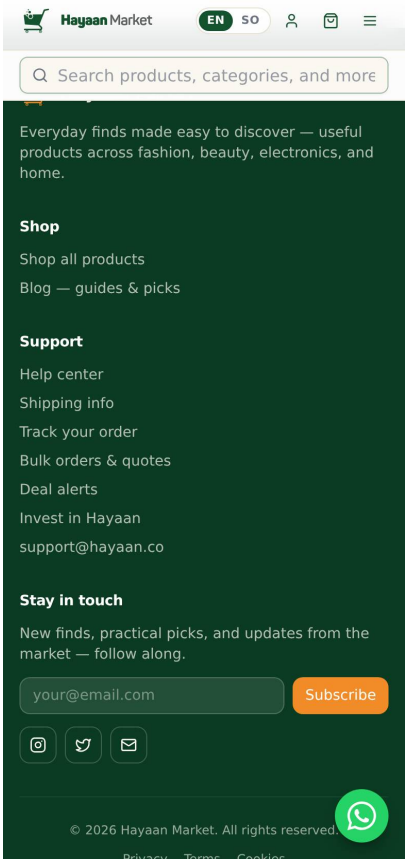

Captures from the live walkthrough of hayaan.co (mobile 390×844 at 2× scale, desktop 1440×900), cross-referenced to the findings they support.

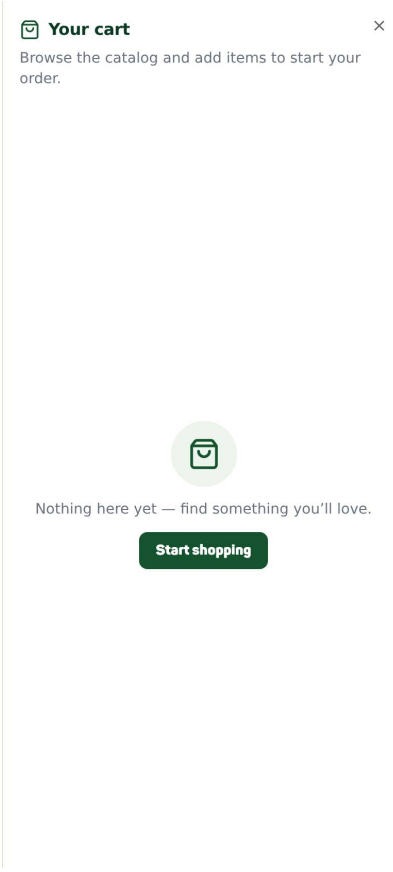

Home on mobile: hero fills about 1.3 viewports before the catalog (F7).

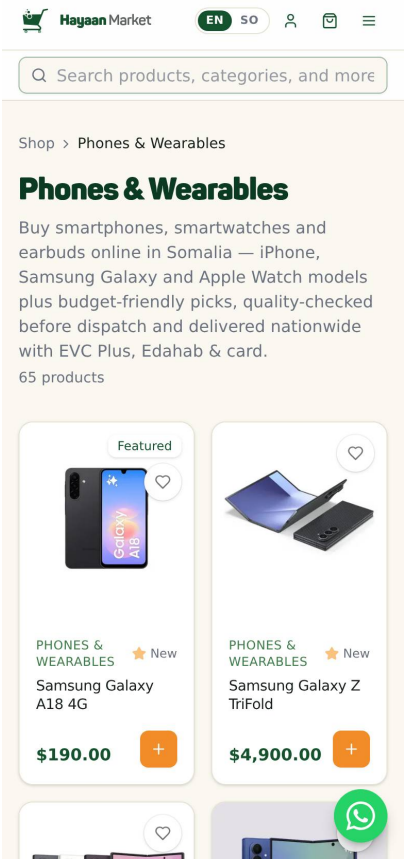

PDP on mobile: clean buy box; no sticky bar once it scrolls away (F6, F9).

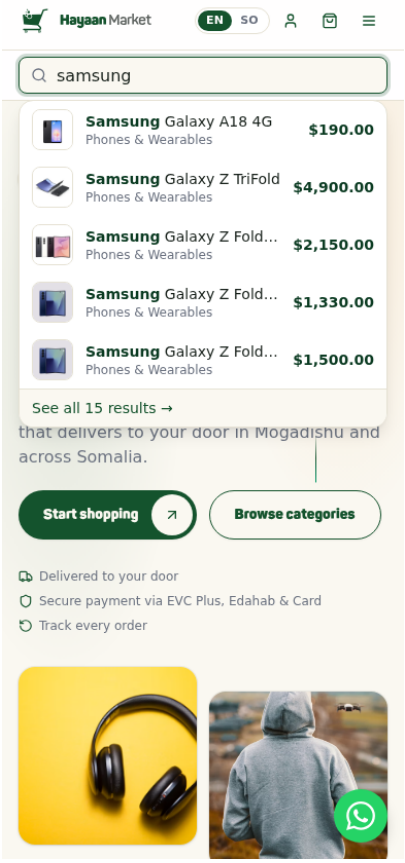

Footer on mobile: help, shipping and policy links are dead text (F4).

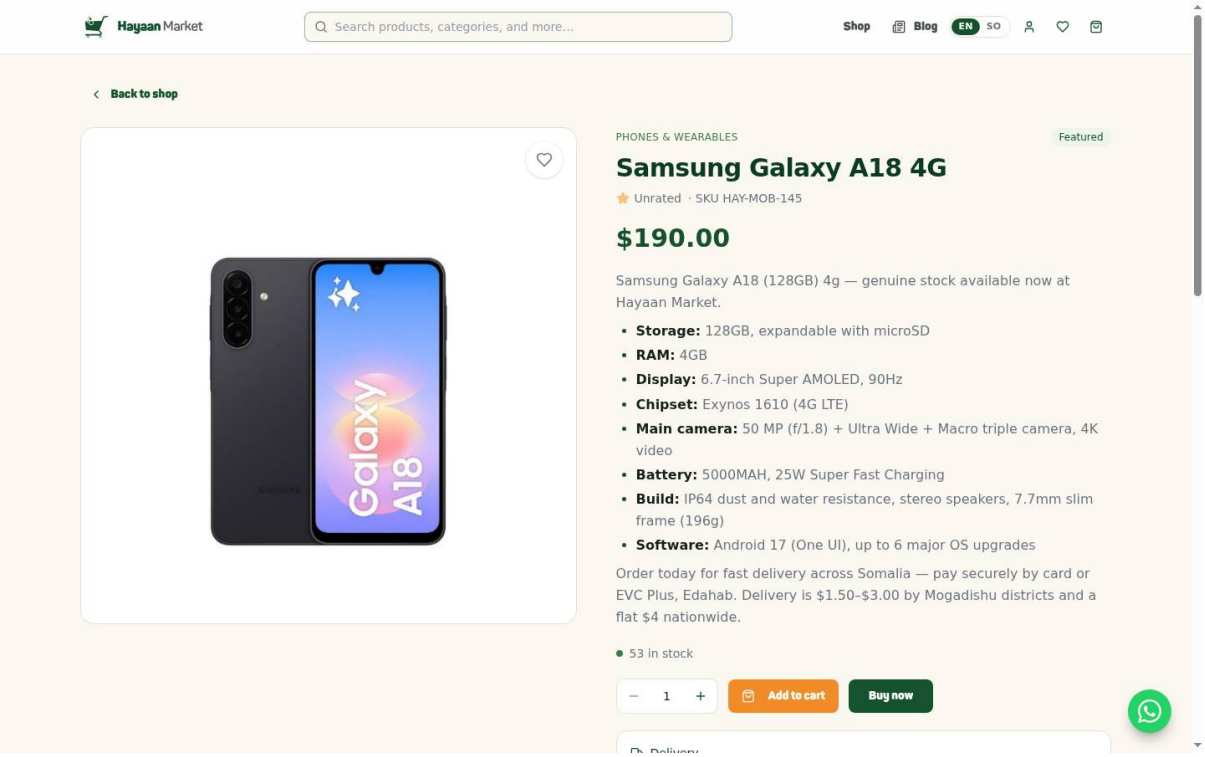

Cart drawer: guests hit a sign-in wall before any item can be added (F1).

Category page: breadcrumb, honest intro and product count (strength).

Live search suggestions on production, mobile (recent fix; strength).

Desktop PDP: quantity, add-to-cart, buy-now, stock and per-district delivery preview (strength).

About this audit. Conducted October 30, 2026 against the production site and the storefront codebase as of commit c6f123c. Live observations were made with scripted real-input browser sessions on the production domain; code observations cite the implementation of the same day. Severity ratings weigh revenue and trust risk for a single-store marketplace at Hayaan's stage; effort ratings assume the current one-developer workflow.
